As it is, Jamiga can be used for some productive stuff. For instance I've got a Java compiler running using Jamiga (which of course is somewhat of a circular usage).

There's also the Twitter client, and a half done Git client (I mention them on the blog). I started working on a Dropbox client, which currently can communicate with Dropbox, but it's not at all integrated with AmigaOS. These examples are basically simple Java programs I've created that uses available Java API:s. So I think there's always some amount of Java coding needed, if we want to utilise some of Java's strength without all of Java implemented.
