GCC need a lot of stack, not tiny bit more a lot of stack...
AmigaOS does not increases stack automatically.

Its also true for many programs, more so on ported Linux programs, because they code without thinking about this.

Crashes is some you expect coding on system with limited memory protection, sometimes you find the bug some time the bug kills AmigaOS4, it can be pretty random, sometime the only way find a bug is printf or serial cable. It always good make testable code that can be isolated.

I sure lot people like to write code, get errors, and not write code, get crash, that is way I think Basic is welcome is some that parity user friendly to beginners, or casual programmers.
