That dos.library note is just saying that dos.library <36 is "special" and is not set up normally due to it primarily being a way to call the internal functions supplied by Tripos.

I don't think that implies you do not need to Forbid()/Permit() when patching  $\geq 36$  functions on any library.

Personally, I think it comes down to the library in question ... Some (like exec) would likely need a Disable if you change functions that can be called from interrupts, otherwise Forbid would be enough. You wouldn't want to change the function right as another program is calling it.
