You could side step this issue with better design XML structure though, your current idea of a space separated list inside a single element is not very structured. And structure is what xml is for. You have no advantage from your xml over plain text, so you might as well have used plain text.

For a more structure xml approach try something more like...

```
<keywords>
<entry class="type">int</entry>
.
.
.
<entry class="function">printf</entry>
</keywords>
```

Construct your own scheme naturally but use one tag for each keyword and add attributes with classnames or similar to associate meta data like what colour or style to render with.
