Hi

Thanks for the insights. Did you end up selling it? Or, if you still have it, would it be possible to check your voltage setting ?

Interesting thing, mine was set to 1.59V and 600MHz from when I got it. However, with memtester it seems to give some errors .. then raising the voltage to 1.64 and all errors gone.. 667MHz speed. Maybe it was too low voltage affecting some memory operations, a bit weird.

I have been running memtester for over 40 hours, and its all good now with no errors for any of the tests. :)
