1) Does the icon appear in the snapshot position after the 2nd iconification? If it does, isn't it a correct behavior then?

Can you explain that one more a bit plz ?

Quote:

2) Does the icon have X/Y coordinates before / after snapshot?

Yes of course it have x/y coordinates after snapshot.

And i found some more info: If icon after snapshotting have X more than 78 (i do not know why exactly that value), then, it didn't show up in the next free slot by Y, but start to show up at top, close to RAM Disk icon. The more i increase X by snapshot the icon, the more iconified icon moves right on the workbench screen.

So it depend exactly on what X value icon have relative to the WB window in which it opened.

Same happens with Y value, if Y value start to be bigger , then icon after iconification placed down a lot.

Dunno if it should be like this ? I somehow think that does not matter where your icons placed in the WB window : when you do iconify, it just should be in the next free slot doesn't not matter what (imho) ?
