When i just do in shell "gvim >ram:test", and then exit from vim, then i have in ram: test file of 0 bytes.

But when i run it from shell i have no output window (as shell is output window as others says), but when i run it from WB (and does not matter how, even just pure binary without icon by dbl-click), it always create me "Output window" with nothing in.

That for sure something in the VIM's initialisation code in amigaos4 ifdefs (or in general amiga ifdefs, just on amigaos4 it reacts like this) from the original os_amiga.c:
