As far as I know, any host on the network can define another host in its hosts table using any hostname it likes. It acts as sort of a local "DNS" on that host.

True, but that's NOT useful, especially when your LAN has a router at its centre that does NOT allow you to set static IP addresses.

Quote:

Why do you need it?

To identify machines on the network in a human readable form in an environment where everyone has a dynamic IP address. The information is there (Avast's Wifi Inspector can read it); I just want to use it.
