For problem 1, if it's a sax parser, then you need to have a buffer that you use to get the data. So you have StartElement () and EndElement () calls that tell you when an element is started and finished. In between them the data handler can get called multiple times, in your case CharacterElement, and you have to append the data chunks together yourself. Does that make sense?

For problem 2, I'd need more info but you should have a lifecycle like

StartElement for Keywords

StartElement for ReservedWords

One or more calls to CharacterElement

EndElement for ReservedWords

EndElement for Keywords
