URL:

Turned off "KeepAlive" in apache to see what happens.

Getting the headers locally on the server does not include the "KeepAlive" parameter as expected.

However from a remote client it is included.

Reading up a bit on it, without claiming to be an expert om it, and it seems that any router between the client and server can handle this on their own. That is, even if the server does not handle KeepAlive the router that your client is speaking to can have its own rules for keeping connections to it reusable.

So in this case it might just be a router between you and the server that handles the connections you make to it. You get the headers as rewritten by the router and not those sent from the server to the first router in the router chain.
