I have a feature request (and hope I didn't overlook it and it's inside already 😊):

1. delay tracing / profiling for X seconds after process start.

This could help to avoid the recording of eventually uninteresting init stuff or lib internal "warm-up" phases.

2. limit tracing / profiling to Y seconds.

This could help to produce better comparable logs.

The reason for both feature-requests is that I suspect that kas1e's latest logs in the GL4ES thread are somewhat "flawed" because they weren't run long enough to "dilute" the warm-up phase of some of the lib's internals, e.g. initial internal VBO setups and such.

Thanks in advance!
