To be honest with you this is a result of things becoming more complicated and developers tend to use frameworks based on JS, to speed up the development. Having in mind that they don't need to optimise anything, because of fast internet and strong computers with a guge amount of ram and plenty of cores, and since noone cares about if it runs on anyones machine as it should. So yeah. Bloated websites with no reason.

And have in mind that everything run on user machine. That's also something that helps to scale to thousands of users at the same time.

I built Mixer.com and Twitch.tv with no CSS and no JS at aiostreams.amiga-projects.net in less than a week, just by using their APIs. The website is super fast and works everywhere without being CPU and memory hungry. The framework I used is based on an up to date PHP framework called Lumen, which is based on Laravel. Everything is running on the server and is super light for the user. The final result is the same, but of course it doesn't look that good. But the thing is that the user wants to find a stream to watch. An he can do that on plain HTML, with the same info presented.
