Sorry for the dumb question, but how can I from ARexx script set the global system variable, so later I can just use it in the prefs:workbench for the screen title format?

I just tried simple "SetVar 1111 2222", a script runs fine, but when I do "setenv" in the shell, to see a list of vars, I didn't see anything from my script.

How can I set it globally? Thanks.

edit: basically does not matter locally, globally, the point is that I can use in prefs:workbench in the screen title "insert/Env variable".
