I'm not sure you need something as complicated a dependency management, it won't be too hard to find the OS version, and check if the program supports it, and only download new package / lha if the program supports the OS version. not sure you need an extra DB, you put min version in the. lha filename.

If OS is updated, you need to bump the min os version, that is also problem as you need to recheck everything.

I think the bigger problem is remembering what stuff is supported in each OS version and update, I'm afraid the only way you truly know if it's not working is if people report problems. Simple solution is bumping the min OS version every time they make new software release, but that might exclude people, who might be able use it.
