Configure files work out shared object extensions by themselves, or at least as an option, Windows doesn't use .so but .dll for example

Yes. But there are only two choices. so and dll. and Amiga is always configured as so since ages. This means patch every configure and is not feasible.

And however .so are the last of the problems. In my ports (all) I always add a SOBJS folder inside the main program that fixes all the possible problems because even with newlib there are always different versions and we don't have a versioning.

Regarding Unix. What do you mean with /T one level up? Can you write me an example using existing functions?
