As Hans suggested, I've replaced my power supply with a new 750W PSU (Corsair RM750 ; 80 plus gold). And I have replaced my memory with a new set of 2x4GB 1600MT/s dimms (Corsair vengeance).

But as expected, this made no difference.

The three issues remain:

1. Warm reset will always result in a cache coheny message and a system halt.- > Annoying but apparently normal behaviour
2. Playing movies, even the ones that were used with testing the driver, result in a random crash of the GFX driver. I have seen four different debug outputs so far for the same movie.
3. 3440x1440 simply doesn't work reliable. Switching to another screenmode will result in no output signal. Manual screenmodes with 3440x1440 doesn't work at all. No matter the update rate.

At this point I will not spend more money on an RX solution. For now I'll stay with my R9 270X and might give it another try when a solution is found or the RX570 and above cards are fully supported.
