Actually i've got it all figured out, the only thing missing is a way to give a variable with differing entries to the loop.

I know there is .KEY, but is there something like .KEY.1(.2,.3 etc.)

That way i could simply enhance a counter (e.g. $i=i+1$) during the loop and simply ask for .KEY.i.

...

I know arexx is far better suited for this (that's why most of the work is done by an arexx script already).

The problem is, that i need to be IN the directory when starting the arexx script, because arexx will only act on the directory it is started in, so i have to copy the rexx script to either directory and that is what i'd like to do in a batch loop.

Right now i mirrored four commands in the batch one after the other, each altering only in the path where the rexx script is copied to and started in.

There has to be a smarter way...
