Your code `_should_` work as you expect and return the signal if that is the reason for `MutexAttemptWithSignal()` returning, or zero if the mutex is obtained.

How do you trigger with the correct signal? It may be you only posted example code and left out the debug output telling you which signal you have to trigger from the outside, but as it is shown here you can't really see the correct signal to send :)

Disclaimer: I've never used the new mutex function, so I don't know more than what the autodocs and examples indicate.
