AFAIK, at the moment you'd better use MEMF\_SHARED memory between your different processes because parent process memory flagged as MEMF\_PRIVATE is not shared with children (NP\_Child) (someone correct me if I'm wrong).

When you say process, do you mean a DOS process, or a task? We're going to have to be very specific with our terminology, or things are going to get very confusing. I'm asking about multiple tasks created by one DOS process.
