It benchmark memory.

To benchmark a cache, just do a memory benchmark, with a buffer size corresponding to the cache size.

When you acces memory, on first loop, the memory is automatically copied in caches. This way, on next loop, the CPU just have to acces caches -> "super speed".

Pegasos 2 does not have L3, and the 7447 have no L3 controller, so... L3 on AmigaOne is also not active. Some tests about this where just making the machine crash, that's why latest batchs of CPU module have no L3, too.
