Thanks for the updates on Timberwolf.

With Timberwolf beta 3, I got a GR on the first launch. Had to reset my system. Worked ok after that, for normal web browsing.

However, I am still having issues with bookmarks. This time I was actually able to save some, although it appears to work differently than I could ever have imagined.

I found that I could add bookmarks if I was running as follows:

- 1) Moved RANDOM: from Storage/DOSDrivers to DEVS:DOSDrivers
- 2) Created CurrentUserProfile on my FFS2 partition
- 3) Set an assign for CurrentUserProfile in my User-StartUp script
- 4) Freed up more RAM and video RAM by changing my Workbench background from my current photo to the old Blue9.jpg

I was able to add three bookmarks, then could not add any others. Each time I attempt to add another bookmark, my system does disk activity, but the bookmarks are not in the bookmark list the next time I launch the program. I cannot figure out where the bookmarks are saved. After many more attempts, I decided to go back to using one of the other web browsers that actually does know how to save bookmarks.

I think that I do not have enough system RAM to use this program to its full potential. Results vary drastically, everytime I launch Timberwolf, and I cannot pinpoint any common denominator other than the amount of system RAM or video RAM that is available when I launch the program.

Update... last experiment...

Power off/on reset

1-3 as above

4) Changed my Workbench background to transparent grey

5) Quit AmiDock

Launched Timberwolf and was able to add another bookmark.

It was in the recent bookmarks list next time I launched Timberwolf.
