I do not doubt that you get 99/100 with the acid test, but I can not reproduce that, and others confirmed to me that they get 100/100 all the time. No one else has reported the 99/100.

So I am assuming some "weird circumstances" cause it for you. Besides, there's little chance I can actually fix it because it is most likely not in the machine dependent code.

The crash is probably due to missing synchronization between subthreads and main thread. They can continue to run while the main thread is exiting (and thus, the main thread frees resources that the subthreads are still using). I'll add a barrier to the thread exit code that should prevent this.

@ mechanic

This bug you describe is most likely also caused by the main thread exiting too early. It should be fixed with the barrier I described above.
