@Chris

Thanks for advices,

I have to include it in contextual menu with an extra argument to make the distinction between "normal fastview" and "singlepicture fastview"

And the only solution to pass extra argument in contextual menu seems to be CLI.

I use Wbstartup structure to take filenames for standard fastview. The complexi for me, is because i want all options to be included in the same executable.

All these new stuffs work now, with installer, deficons replace (with backup the first time)...

-for drawer, it's the standard fastview who handles it.

-multi-file in singlepicture, except the possibility to start muli instance of singlepicture, i don't want (know how) to manage a lot of dinamically created windows in my program.
